- → Perfect Backwarding

PART I

Understanding References

```
#!/usr/bin/env python3
3
   class S:
        def init (self, x):
            self.x = x
6
7
   def swap(a, b):
        b, a = a, b
9
10
   if __name__ == '__main__':
       a, b = S(1), S(2)
11
12
       swap(a, b)
13
        print(f'{a.x}{b.x}')
```

```
#include <iostream>
    struct S {
        int x;
 5
    void swap(S& a, S& b) {
        S\& tmp = a;
        a = b;
10
        b = tmp:
11
12
13
    int main() {
14
        S a{1}; S b{2};
15
        swap(a, b);
16
        std::cout << a.x << b.x;
17
```

godbolt.org/z/rE6Ecd

```
#include <iostream>
   struct S {
        int x;
    };
5
6
   void swap(S& a, S& b) {
        S tmp = a;
        a = b;
        b = tmp;
10
11
12
   int main() {
13
14
        S a{1}; S b{2};
        swap(a, b);
15
        std::cout << a.x << b.x;
16
17
```

godbolt.org/z/r6oq55

```
#include <iostream>
 2
    struct S {
        int x;

Binding references to temporaries

error: cannot bind non-const Ivalue reference of type "S*&" to an rvalue of type "S*"

- → Memory addresses are always rvalues!
- → One cannot refer to something that doesn't has a name...
- → ...except it is a const reference (lifetime extension)

std::move

std::move

godbolt.org/z/aKbGEc

- → std::move creates xvalues
- → Syntax:
 - → Ivalue ref.: S&
 - → rvalue ref.: S&&

```
#include <iostream>
   #include <utility>
    struct S{
        S() { std::cout << 'a'; }
        S(const S&) { std::cout << 'b'; }
        S(S&&) { std::cout << 'c'; }
8
    };
9
10
    int main() {
        S s1;
11
        S s2(s1);
12
        S s3(S{});
13
        S s4(std::move(s1));
14
15
```

godbolt.org/z/16hYbz

A: abac

```
#include <iostream>
   #include <utility>
   struct S{
       S() { std::cout << 'a'; }
       S(const S&) { std::cout << 'b'; }
       S(S&&) { std::cout << 'c'; }
8
   };
   int main() {
       S s1;
       S s2(s1);
       S s3(S{});
       S s4(std::move(s1));
14
15
```

godbolt.org/z/16hYbz

- → S s1: no surprise
- \rightarrow S s2(s1): no surprise
- → S s3(S{}): mandatory copy elision (initializer is prvalue of the same class type)
- → S s4(std::move(s1)): forced move construction

```
#include <iostream>
   #include <utility>
    struct S {
        S() { std::cout << 'a'; }
        S(const S&) { std::cout << 'b'; }
        S(S&&) { std::cout << 'c'; }
8
    };
9
   void f(const S&) { std::cout << '1'; }</pre>
10
   void f(S&) { std::cout << '2'; }</pre>
    void f(S&&) { std::cout << '3'; }</pre>
12
13
    int main() {
14
15
        S s1;
        f(s1);
16
17
        f(S{});
        f(std::move(s1));
18
19
```

godbolt.org/z/4MKojT

```
#include <iostream>
    #include <utility>
    struct S {
        S() { std::cout << 'a'; }
        S(const S&) { std::cout << 'b'; }
        S(S&&) { std::cout << 'c'; }
8
    };
9
    void f(const S&) { std::cout << '1'; }</pre>
10
    void f(S) { std::cout << '2'; }</pre>
    void f(S&&) { std::cout << '3'; }</pre>
12
13
    int main() {
14
15
        S s1;
        f(s1);
16
17
        f(S{});
        f(std::move(s1));
18
19
```

godbolt.org/z/jaYTYP

```
#include <iostream>
    #include <utility>
    struct S {
        S() { std::cout << 'a'; }
        S(const S&) { std::cout << 'b'; }</pre>
        S(S&&) { std::cout << 'c'; }
8
    };
    void f(const S&) { std::cout << '1'; }</pre>
    void f(S) { std::cout << '2'; }</pre>
    void f(S&&) { std::cout << '3'; }</pre>
12
13
    int main() {
14
15
        S s1:
        f(s1);
16
        f(S{});
        f(std::move(s1));
18
19
```

godbolt.org/z/jaYTYP

Compile-time error (in all three cases)

- \rightarrow f(s1): ambiguity between 2 and 1
- \rightarrow f(S{}): ambiguity between 2 and 3
- → f(std::move(s1): same as f(S)
- ⇔ compiler cannot differentiate between copy and reference overloads! (neither lvalue, nor rvalue)

```
#include <iostream>
    #include <utility>
    struct S {
 5
        ~S() { std::cout << 'a'; }
6
7
    };
    void f(const S&) { std::cout << '1'; }</pre>
    void f(S&) { std::cout << '2'; }</pre>
    void f(S&&) { std::cout << '3'; }</pre>
10
11
    int main() {
12
        S\&\& r1 = S\{\};
13
        f(r1);
14
15
        S\&\& r2 = S\{\};
16
17
        f(std::move(r2));
18
```

godbolt.org/z/5s1zc5

A: 23aa

```
#include <iostream>
    #include <utility>
    struct S {
        ~S() { std::cout << 'a'; }
    };
    void f(const S&) { std::cout << '1'; }</pre>
    void f(S&) { std::cout << '2'; }</pre>
    void f(S&&) { std::cout << '3'; }</pre>
10
11
12
    int main() {
13
        S\&\& r1 = S\{\};
14
        f(r1);
15
16
        S\&\& r2 = S\{\};
        f(std::move(r2));
17
18
```

godbolt.org/z/5s1zc5

- → S&&: object that nobody cares about anymore and which will die soon (cf. lifetime extension!)
- → std::move does not actually kill, but makes the object look like a dying object

NB: an rvalue ref behaves like an Ivalue ref except that it can bind to a temporary (an rvalue), whereas one cannot bind a (non const) Ivalue ref to an rvalue.

std::move

```
#include <type_traits>

template <typename T>
decltype(auto) move(T&& t) {
    using R = std::remove_reference_t<T>&&;
    return static_cast<R>(t);
}
```

godbolt.org/z/W8zb8G

So what does std::move?

- → does not move
- → does not destroy
- → does nothing at all during runtime
- → unconditionally casts its argument to an rvalue

Quick Bench: tinyurl.com/y67sg7to

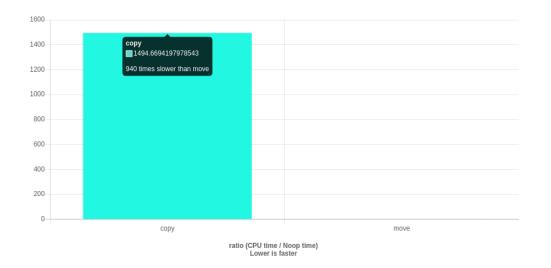

```
std::vector<int> x(1000, 42);
std::vector<int> y(1000, 42);

for (auto _ : state) {
    auto tmp = x;
    x = y;
    y = tmp;
    benchmark::DoNotOptimize(x[345] + y[678]);
}
```

```
std::vector<int> x(1000, 42);
std::vector<int> y(1000, 42);

for (auto _ : state) {
    auto tmp = std::move(x);
    x = std::move(y);
    y = std::move(tmp);
    benchmark::DoNotOptimize(x[345] + y[678]);
}
```

Quick Bench: tinyurl.com/y67sg7to

Universal References

Rvalue ref. or no rvalue ref.?

Rvalue refs are declared using "&&": reasonable to assume that the presence of "&&" in a type declaration indicates an rvalue reference?

```
struct S{};
S\&\& s = S{};
                             // (1)
auto\&\& s2 = s;
                             // (2)
void f(S&& s);
                             // (3)
template <typename T>
void f(T\&\& t);
                             // (4)
template <typename T>
void f(const T&& t);
                             // (5)
template <typename T>
void f(std::vector<T>&& v); // (6)
```

Does "&&" mean rvalue reference?

- → (1): ???
- → (2): ???
- → (3): ???
- → (4): ???
- → (5): ???
- → (6): ???

Rvalue ref. or no rvalue ref.?

Rvalue refs are declared using "&&": reasonable to assume that the presence of "&&" in a type declaration indicates an rvalue reference?

```
struct S{};
S\&\& s = S\{\};
                             // (1)
auto\&\& s2 = s;
                             // (2)
void f(S&& s);
                             // (3)
template <typename T>
void f(T\&\& t);
                             // (4)
template <typename T>
void f(const T&& t);
                             // (5)
template <typename T>
void f(std::vector<T>&& v); // (6)
```

Does "&&" mean rvalue reference?

- → (1):
- → (2):
- → (3):
- → (4):
- → (5):
- → (6):

^{*} albeit questionable: move changes object in most cases ↔ const

std::move and const

```
#include <iostream>

struct S {
    S() {}
    S(const S&) { std::cout << 'A'; }
    S(S&&) { std::cout << 'B'; }
};

int main() {
    const S s;
    auto s2 = std::move(s);
}
</pre>
```

godbolt.org/z/r9hv8K

...prints A

(cf. https://stackoverflow.com/a/28595415)

Universal references

Universal references[†]

- → Syntax (x is a universal reference):
 - → auto&& x
 - → template <typename T>
 f(T&& x...
- → Rule of thumb: substitute fully qualified type into auto or T and reduce:
 - \rightarrow && \mapsto &&
 - \rightarrow &&& \mapsto &
 - \rightarrow &&&& \mapsto &&

```
std::vector<S> v;

auto&& s = v[0]; // S&&& -> S&

auto&& s2 = S{}; // S&&& -> S&

auto&& s3 = s2; // S&& -> S&

// S&&& -> S&

auto&& s3 = std::move(s2);

/* Exception */

S s4{};

auto&& s5 = s4; // S&& -> S&
```

Universal reference are always references!

[†] *Universal reference*: term introduced by Scott Meyers

```
#include <iostream>
   #include <type traits>
   struct S {
        S() { std::cout << 'a'; }
        S(const S&) { std::cout << 'b'; }
        S(S&&) { std::cout << 'c'; }
8
   };
9
10
   template <typename T>
   S f(T&& t) { return t; }
11
12
13
   int main() {
        S s{};
14
        f(s);
15
        f(std::move(s));
16
17
```

godbolt.org/z/6xn1n3

```
#include <iostream>
   #include <type traits>
   struct S{};
 5
    void f(S&) { std::cout << 'a'; }</pre>
   void f(S&&) { std::cout << 'b': }</pre>
8
    int main() {
10
        auto&& r1 = S\{\};
        static assert(std::is_same_v<decltype(r1), S&&>);
11
12
        f(r1);
        f(static cast<S&&>(r1));
13
14
15
        Ss;
        auto\&\& r2 = s;
16
17
        static_assert(std::is_same_v<decltype(r2), S&>);
        f(r2);
18
19
```

godbolt.org/z/zTExze

```
#include <iostream>
    struct S{
        void f() & { std::cout << 'a'; }</pre>
        void f() && { std::cout << 'b'; }</pre>
    };
    int main() {
        auto&& r1 = S\{\};
10
        r1.f();
        static cast<decltype(r1)>(r1).f();
11
12
13
        auto&& r2 = r1;
        r2.f();
14
15
        static_cast<decltype(r2)>(r2).f();
16
```

godbolt.org/z/WcYYsd

Perfect forwarding

How do we fuse these implementations?

```
// if `t` is an lvalue of type `T`
template <typename T> T& forward(T& t) {
    return t;
}

// if `t` is an rvalue of type `T`
template <typename T> T&& forward(T& t) {
    return std::move(t); // static_cast<T&&>(t)
}
```

```
#include <type_traits>

template <typename T>
T&& forward(std::remove_reference_t<T>& t) {
    return static_cast<T&&>(t);
}
```

godbolt.org/z/EjPnPr

```
#include <iostream>
   #include <type traits>
   struct S {
        S() { std::cout << 'a'; }
        S(const S&) { std::cout << 'b'; }
        S(S&&) { std::cout << 'c'; }
8
    };
9
10
   template <typename T>
   S f(T\&\& t) { return std::forward<T>(t); }
11
12
13
   int main() {
        S s{};
14
        f(s);
15
        f(std::move(s));
16
17
```

godbolt.org/z/7Worb3

A: abc

```
#include <iostream>
   #include <type traits>
   struct S {
        S() { std::cout << 'a'; }
        S(const S&) { std::cout << 'b'; }
        S(S&&) { std::cout << 'c'; }
8
   };
9
10
   template <typename T>
   S f(T&& t) { return std::forward<T>(t); }
11
12
   int main() {
13
        S s{};
14
        f(s);
15
        f(std::move(s));
16
17
```

godbolt.org/z/7Worb3

Rule of thumb: Use std::move for rvalues and std::forward for universal references

Q: Why can't we use perfect forwarding here?

```
#include <functional>

template <typename Iter, typename Callable, typename... Args>
void foreach (Iter current, Iter end, Callable op, const Args&... args) {
    while (current != end) {
        std::invoke(op, args..., *current);
        ++current;
    }
}
```

godbolt.org/z/TvnEfT

Reading x86-64 Assembly ...for fun and profit

Function Prologue & Epilogue

- → Few lines of code at the beginning (*prologue*) and end (*epilogue*) of a function, which **prepares** (and eventually restores)
 - → the stack and
 - → registers
- → Not part of assembly: convention (defined & interpreted differently by different OS and compilers)

Prologue

alternatively

```
1 enter N, 0
```

(reserve N bytes on stack for local use)

Epilogue

```
1 mov rsp, rbp
2 pop rbp
3 ret
```

alternatively

```
1 leave
2 ret
```

Stack frame for function call

- → CALL = PUSH address of next instruction + JMP target
- → RET pops return address and transfers control there
- → pass arguments 1 ...6 in registers (rsi, rdx, ...)

```
8th Argument
                (rbp + 24)
                (rbp + 16)
7th Argument
                (return address)
rip
rbp
                (rbp)
rhx
r12
r13
                (rsp)
```

(stack frame for function call with 8 arguments and local registers rbx, r12 and r13)

lea vs. mov

- → lea: load effective address
- → puts memory address from STC into the destination dest
- → Example: lea eax, [ebx+8]
 - → put [ebx+8] into eax
 - → value of eax after instruction: 0x00403A48
- → ...whereas: mov eax, [ebx+8]
 - → value of eax after instruction: 0x0012C140

Registers

 $EAX = 0 \times 000000000$

 $EBX = 0 \times 00403A40$

Memory

0x7C81776F

0x7C911000

0x0012C140

0x7FFDB000

 $0 \times 00403A40$

 $0 \times 00403A44$

0x00403A48

0x00403A4C

```
int f(int x, int y, int z) {
   int sum = x + y + z;
   return sum;

6 I
6
      sub eax, DWORD PTR [rbp-20]
 71
      leave
 7|
      ret
```

godbolt.org/z/5xq5n5

```
# q92 -00
    f(int const&):
      push rbp
      mov rbp, rsp
      sub rsp, 32
      mov QWORD PTR [rbp-24], rdi
      mov rax, OWORD PTR [rbp-24]
      mov eax, DWORD PTR [rax]
      mov DWORD PTR [rbp-4], eax
      call side effect()
 6 İ
      mov rax, QWORD PTR [rbp-24]
 6|
      mov eax, DWORD PTR [rax]
      mov edx, DWORD PTR [rbp-4]
 61
      sub edx, eax
 6|
      mov eax, edx
      leave
      ret
```

godbolt.org/z/333ME7

```
# g92 -03
  | f(int):
3| sub rsp, 8
5| call side_effect()
7| xor eax, eax
7| add rsp, 8
7| ret
```

godbolt.org/z/od8v6e

NB #1: adjusting rsp in function prologue necessary when function is not a leaf function since callee have to know where to start saving variables on stack. (Adjusting rsp can be ommitted in leaf functions.)

```
# q92 -03
    f(int const&):
      push rbp
      push rbx
      mov rbx, rdi
 3 İ
      sub rsp, 8
      mov ebp, DWORD PTR [rdi]
      call side effect()
 6 İ
      mov eax, ebp
 6 I
      sub eax, DWORD PTR [rbx]
      add rsp, 8
      pop rbx
      pop rbp
      ret
```

godbolt.org/z/cr8f9b

```
# g92 -03
  | f(int):
3| sub rsp, 8
5| call side_effect()
7| xor eax, eax
7| add rsp, 8
7| ret
```

godbolt.org/z/od8v6e

NB #2: Offset x in Sub rsp, x is objective of optimizations such as alignment: ABI requires stack to be aligned to 16 bytes.

```
# q92 -03
    f(int const&):
      push rbp
      push rbx
      mov rbx, rdi
 3 İ
      sub rsp, 8
      mov ebp, DWORD PTR [rdi]
      call side effect()
 6
      mov eax, ebp
      sub eax, DWORD PTR [rbx]
      add rsp, 8
      pop rbx
      pop rbp
      ret
```

godbolt.org/z/cr8f9b

```
#include <string>
#include <string_view>

auto get_size(const std::string& s) {
    return s.size();
}

auto get_size(std::string_view sv) {
    return sv.size();
}
```

godbolt.org/z/Yc1hrj

```
# clang900 -03 -std=c++2a -stdlib=libc++
    get size(std::string const&):
      movzx eax, byte ptr [rdi]
XX I
     test al, 1
xx l
     ie .LBB0 1
xx|
      mov rax, gword ptr [rdi + 8]
      ret
    .LBB0 1:
      shr rax
      ret
    get size(std::string view):
      mov rax, rsi
      ret
```

godbolt.org/z/Yc1hrj

Even though we *only* pass a reference, we pay the cost of the complex object std::string (i.e., first bit is tested for short string optimization)

→ prefer views such as std::string_view or std::span

```
#include <string>
#include <string_view>

auto get_size(const std::string& s) {
    return s.size();
}

auto get_size(std::string_view sv) {
    return sv.size();
}
```

godbolt.org/z/Yc1hrj

```
# clang900 -03 -std=c++2a -stdlib=libc++
   get size(std::string const&):
xx|
     movzx eax, byte ptr [rdi]
xx| test al, 1
    je .LBB0 1
xx l
     mov rax, gword ptr [rdi + 8]
      ret
    .LBB0 1:
      shr rax
     ret
   get_size(std::string_view):
     mov rax, rsi
      ret
```

godbolt.org/z/Yc1hrj

*Confession: switching to libstdc++ resolves this issue here

godbolt.org/z/66exs6

```
template <typename T, std::size_t N>
constexpr span(const std::array<T, N>& arr) noexcept;
```

cppreference.com/w/cpp/container/span/span

godbolt.org/z/66exs6

No!

- → Constructor takes by reference
- → References to automatic storage objects are not constant expressions!
- → Solutions?

```
template <typename T, std::size_t N>
constexpr span(const std::array<T, N>& arr) noexcept;
```

cppreference.com/w/cpp/container/span/span

```
#include <array>
#include <span>

int main() {
    constexpr static std::array x{
        4, 8, 15, 16, 23, 42
    };
    constexpr std::span x_view{x};
}
```

godbolt.org/z/Ga5Ysv

Nota bene ...

this will work though, since reference / pointer does not escape constant expression ...

```
#include <array>
#include <span>

constexpr auto f() {
    std::array x{4, 8, 15, 16, 23, 42};
    std::span x_view{x};
    return 0;
}

int main() {
    static_assert(f() == 0);
}

#include <array>

```

godbolt.org/z/rso3na

PART II

Dangling References

```
struct S {
2
3
4
        int x;
    };
5
    auto f() {
        S s{.x = 42};
        return s;
8
9
10
    int main() {
11
        S\& s = f();
        return s.x;
12
13
```

godbolt.org/z/x4rWKj

Will it invoke undefined behavior?

```
1  struct S {
2    int x;
3  };
4  
5  auto f() {
6    S s{.x = 42};
7   return s;
8  }
9  
10  int main() {
11   const S& s = f();
12   return s.x;
13 }
```

godbolt.org/z/avGMPa

...binding a reference to a temporary???

Temporary object lifetime extension

```
struct S {
        int x;
    };
5
    auto f() {
        S s{.x = 42};
        return s;
 8
9
10
    int main() {
        const S\& s = f();
11
12
        return s.x;
13
```

godbolt.org/z/avGMPa

cppreference.com: "The lifetime of a temporary object may be extended by binding to a const lvalue reference or to an rvalue reference (since C++11)."

```
#include <iostream>
 2
   template <char id> struct Log {
        Log() { std::cout << id << 1; }
        virtual ~Log() { std::cout << id << 2; }</pre>
   };
    struct A: Log<'a'> {
        int x;
        A(int x): x(x) \{\};
10
   struct B: Log<'b'> {
11
        const A& a;
12
        B(const A& a): a(a) {}
13
   };
14
15
    int main() {
16
17
        const B& b = B\{A\{42\}\};
        std::cout << 'x';
18
19
        return b.a.x;
20
```

godbolt.org/z/hcods4

A: a1b1a2xb2

```
#include <iostream>
 3
   template <char id> struct Log {
        Log() { std::cout << id << 1; }
        virtual ~Log() { std::cout << id << 2; }</pre>
   struct A: Log<'a'> {
        int x;
        A(int x): x(x) \{\};
10
    struct B: Log<'b'> {
        const A& a;
12
        B(const A& a): a(a) {}
   };
14
15
16
   int main() {
17
        const B& b = B\{A\{42\}\};
        std::cout << 'x';
18
        return b.a.x;
20
```

godbolt.org/z/hcods4

Dangling reference!!!

- → lifetime extension only for result of the temporary expression, not any sub-expression
- → use address sanitizer!

contrived?

Reference lifetime extension

(derived from abseil.io: Tip of the Week #107: "Reference Lifetime Extension")

```
std::vector<std::string_view> explode(const std::string& s);
for (std::string_view s: explode(str_cat("oo", "ps"))) { // WRONG!
[...]
```

Q: What is the output of the program?

```
#include <vector>
int main() {
    std::vector<int> v;
    v.push_back(1);
    auto& x = v[0];
    v.push_back(2);
    return x;
}
```

godbolt.org/z/M6bx1Y

Q: What is the output of the program?

```
#include <vector>

int main() {
    std::vector<int> v;
    v.push_back(1);
    auto& x = v[0];
    v.push_back(2);
    return x;
}
```

godbolt.org/z/M6bx1Y

Dangling reference!!!

- → std::vector needs to reallocate all the space the second time an element is pushed
- → use address sanitizer!

std::move in the wild

(derived from CppCon 2019: Ben Deane "Everyday Efficiency: In-Place Construction (Back to Basics?)")

```
static void cp_small_str(benchmark::State& state) {
   for (auto _ : state) {
      std::string original("small");
      benchmark::DoNotOptimize(original);
      std::string copied = original;
      benchmark::DoNotOptimize(copied);
   }
}
BENCHMARK(cp_small_str);
```

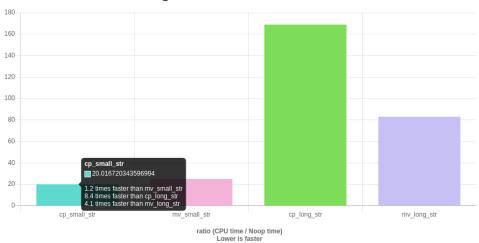

```
static void mv_small_str(benchmark::State& state) {
   for (auto _ : state) {
       std::string original("small");
       benchmark::DoNotOptimize(original);
       std::string moved = std::move(original);
       benchmark::DoNotOptimize(moved);
   }
}
BENCHMARK(mv_small_str);
```

(derived from CppCon 2019: Ben Deane "Everyday Efficiency: In-Place Construction (Back to Basics?)")

```
static void cp_long_str(benchmark::State& state) {
   for (auto _ : state) {
      std::string original("this is too long for short string optimization");
      benchmark::DoNotOptimize(original);
      std::string copied = original;
      benchmark::DoNotOptimize(copied);
   }
}
BENCHMARK(cp_long_str);
```

```
static void mv_long_str(benchmark::State& state) {
   for (auto _ : state) {
      std::string original("this is too long for short string optimization");
      benchmark::DoNotOptimize(original);
      std::string moved = std::move(original);
      benchmark::DoNotOptimize(moved);
   }
}
BENCHMARK(mv_long_str);
```

Lower is faster

Quick Bench: tinyurl.com/yybmdngv

Copy small std::string

1. copy stack allocated data

Move small std::string

- 1. copy stack allocated data
- **2.** set string length of moved string to zero

→ moving is not necessarily better than copying!

Did they forget to mark the move ctor noexcept?

```
// since C++11
std::map(const std::map&&)
// until C++17
std::map& operator=(std::map&&)
// since C++17
std::map& operator=(std::map&&) noexcept
```

Did they forget to mark the move ctor noexcept? No!

```
// since C++11
std::map(const std::map&&)
// until C++17
std::map& operator=(std::map&&)
// since C++17
std::map& operator=(std::map&&) noexcept
```

- → Move ctor needs to allocate new sentinel node, because moved from container must still be a valid container (albeit in an unspecified state)
- → Move assignment can swap, thus no need to allocate

 \hookrightarrow move ctor of std::map allocates heap space!

(Billy O'Neal: twitter.com/MalwareMinigun/status/1165310509022736384)

```
static void rvo(benchmark::State& state) {
    for (auto _ : state) {
        auto m = []() -> std::map<int, int> {
            std::map<int, int> m{{0, 42}};
            return m;
        }();
        benchmark::DoNotOptimize(m);
    }
}
BENCHMARK(rvo);
```

```
static void fmove(benchmark::State& state) {
    for (auto _ : state) {
        auto m = []() -> std::map<int, int> {
            std::map<int, int> m{{0, 42}};
            return std::move(m);
        }();
        benchmark::DoNotOptimize(m);
    }
}
BENCHMARK(fmove);
```

```
static void copy(benchmark::State& state) {
    for (auto _ : state) {
        std::map<int, int> m{{0, 42}};
        benchmark::DoNotOptimize(m);
        auto m2 = m;
        benchmark::DoNotOptimize(m2);
    }
}
BENCHMARK(copy);
```

Quick Bench: tinyurl.com/y57egvjp

Why?

Does this code bother anyone?

```
#include <cstddef>
   #include <type traits>
   #include <utility>
   template <typename T>
   struct Data final {
       T *data;
       explicit Data(const std::size_t size): data(new T[size]) {}
       ~Data() { delete [] data; }
10
   };
11
   auto init() {
12
       Data<int> d(3);
13
       d.data[0] = 1; d.data[1] = 2; d.data[2] = 3;
14
        return d;
15
16
17
   int main() { return init().data[2]; }
18
```

godbolt.org/z/j19Pbq

What happens on return?

Interlude

Will it compile?

```
struct A {
        int x;
 3
4
        A(int x, int y = 0) : x(x + y) \{ \}
   };
5
6
    struct B {
        int x;
        explicit B(int x, int y = 0) : x(x + y) {}
8
   };
10
11
   template <typename T>
12
    T init() { return 42; }
13
    int main() {
14
      auto x = init < A > ().x;
15
      auto y = init<B>().x;
16
17
```

godbolt.org/z/vYab6f

Implicit conversion to the function return type

Implicit conversion

- → ...if ctor is **not** marked explicit
- → Examples:

```
→ std::optional(T&&)
```

```
→ std::string(const char*)
```

```
#include <optional>
#include <string>

std::optional<int> f() {
    return 42;
}

std::string g() {
    return "foo";
}
```

godbolt.org/z/bh4svz

Q: What is the output of the program?

Compiler flags: -std=c++14 -fno-elide-constructors

```
#include <iostream>
   struct S {
       S() { std::cout << 'a'; }
       S(const S&) { std::cout << 'b'; }
        S(const S&&) { std::cout << 'c'; }
        S& operator=(const S&) { std::cout << 'd'; return *this; }
        S& operator=(const S&&) { std::cout << 'e'; return *this; }
   };
10
   S f() { return S{}; }
11
12
   int main() {
13
14
       S s(S{}); std::cout << ", ";
       auto s1 = f(); std::cout << ", ";
15
       auto s2{f()};
16
17
```

godbolt.org/z/xxb9xe

Q: What is the output of the program?

Compiler flags: -std=c++17

```
#include <iostream>
   struct S {
       S() { std::cout << 'a'; }
       S(const S&) { std::cout << 'b'; }
        S(const S&&) { std::cout << 'c'; }
       S& operator=(const S&) { std::cout << 'd'; return *this; }
        S& operator=(const S&&) { std::cout << 'e'; return *this; }
   };
10
   S f() { return S{}; }
11
12
   int main() {
13
14
       S s(S{}); std::cout << ", ";
       auto s1 = f(); std::cout << ", ";
15
       auto s2{f()};
16
17
```

godbolt.org/z/7oPa4Y

Why?

Ben Deane: "Perhaps the most important optimization the compiler does"

Copy Elision

```
struct S {
    S() = default;
    S(const S&) = delete;
    S& operator=(const S&) = delete;
};

S f() { return S{}; }

int main() {
    S s(S{});
    auto s1 = f();
    auto s2{f()};
}
```

godbolt.org/z/ThqjzP

Mandatory elision of copy/move operations since C++17):

- → Return statement: when operand is a prvalue of same class type as return type
- → Initialization of a variable: when initializer expression is a prvalue of same class type as the variable type

...even if the copy/move constructor and the destructor has observable side-effects!

Rule of thumb: avoid naming return values

RVO in Depth

C++ Objects in Assembly

```
struct S final {
        int a, b, c;
 4
        S(int a, int b, int c) noexcept:

```

godbolt.org/z/v5ro3q

```
→ g1: ???→ g2: ???→ g3: ???→ q4: ???
```

(derived from CppCon 2019: Jason Turner "Great C++ is_trivial")

No (N)RVO in any of these examples!

```
S g1() { auto [s1, s2] = f(); return s1; } // copy
S g2() { auto&& [s1, s2] = f(); return s1; } // copy: no implicit move yet (?)
S g3() { auto [s1, s2] = f(); return std::move(s1); } // move
S g4() { auto&& [s1, s2] = f(); return std::move(s1); } // move
```

...return std::move is not always bad

Why? Structured bindings:

- → Creation of temporary object e
- → Like a reference: structured binding is an alias into e

Implicit move

return std::move is not yet necessarily a code smell

(use -Wpessimizing-move)

Automatic move from local variables and parameters if:

- → return expression names a variable whose type is either
 - → an object type or (since C++11)
 - → an rvalue reference to object type (since C++20*)
- → ...and that variable is declared
 - → in the body or
 - → as a parameter of
- → ...the innermost enclosing function or lambda expression

^{*} P1825R0 (not yet implemented in GCC or Clang: cppreference.com/w/cpp/compiler_support)

Perfect Backwarding

(derived from CppCon 2018: Hayun Ezra Chung "Forwarding Values... and Backwarding Them Too?")

```
#include <iostream>
   #include <memorv>
   struct Resource {}:
5
   struct Target {
        Target(const Resource&) { std::cout << 'a'; }</pre>
        Target(Resource&&) { std::cout << 'b': }</pre>
9
   };
10
   auto make_target(??? resource) {
11
        return std::make unique<Target>(???);
12
13
14
15
   int main() {
16
        Resource resource;
17
        make target(resource);
                                // should print 'a'
        make target(Resource(resource)); // should print 'b'
18
        make target(std::move(resource)); // should print 'b'
19
20
```

godbolt.org/z/WMPGGq

(derived from CppCon 2018: Hayun Ezra Chung "Forwarding Values... and Backwarding Them Too?")

```
#include <iostream>

11
12
   };
13
   int main() {
14
15
        ResourceManager rm:
        Target(rm.visit([](Resource& r) -> Resource& { return r; }));
16
17
        Target(rm.visit([](Resource& r) -> Resource { return r; }));
        Target(rm.visit([](Resource& r) -> Resource&& { return std::move(r); }));
18
19
```

godbolt.org/z/f56vaP

```
#include <iostream>
   struct Resource {};
   struct ResourceManager {
5
        Resource resource:
        // what if we want to do sth. with the result before returning?
        decltype(auto) visit(auto visitor) { return visitor(resource); }
   };
   struct Target {
10
        Target(const Resource&) { std::cout << 'a'; }</pre>
11
        Target(Resource&&) { std::cout << 'b'; }</pre>
12
13
   };
14
15
   int main() {
16
        ResourceManager rm;
        Target(rm.visit([](Resource& r) -> Resource& { return r; }));
17
        Target(rm.visit([](Resource& r) -> Resource { return r; }));
18
        Target(rm.visit([](Resource& r) -> Resource&& { return std::move(r); }));
19
20
```

godbolt.org/z/35zbYW

Q: Why is this a bad idea?

```
auto&& visit(auto visitor) {
   auto&& result = visitor(resource);
   return result;
}
```

Q: Why is this a bad idea?

```
auto&& visit(auto visitor) {
    auto&& result = visitor(resource);
    return result;
}
```

A: Dangling reference for

```
visit([](Resource& r) -> Resource { return r; }));
```

auto&& is always a reference!

```
#include <iostream>
    struct Resource {};
    struct ResourceManager {
 5
        Resource resource:
        ??? visit(auto visitor) {
            ??? result = visitor(resource);
            return ???;
10
    };
11
    struct Target {
12
        Target(const Resource&) { std::cout << 'a'; }</pre>
13
        Target(Resource&&) { std::cout << 'b'; }</pre>
14
15
    };
16
17
    int main() {
18
        ResourceManager rm;
19
        Target(rm.visit([](Resource& r) -> Resource { return r; }));
20
```

godbolt.org/z/d1WeqT

```
#include <iostream>
    struct Resource {};
    struct ResourceManager {
        Resource resource:
        Resource visit(auto visitor) {
            Resource result = visitor(resource);
            return result:
    };
    struct Target {
        Target(const Resource&) { std::cout << 'a'; }</pre>
13
        Target(Resource&&) { std::cout << 'b'; }</pre>
14
15
    };
16
    int main() {

How do we fuse these implementations?

```
Resource visit(auto visitor) {
        Resource result = visitor(resource);
        return result;
5
   Resource& visit(auto visitor) {
        Resource& result = visitor(resource);
        return result;
10
11
   Resource&& visit(auto visitor) {
        Resource&& result = visitor(resource);
12
        return static cast<Resource&&>(result);
13
14
```

```
Target(rm.visit([](Resource& r) -> Resource { return r; }));
Target(rm.visit([](Resource& r) -> Resource& { return r; }));
Target(rm.visit([](Resource& r) -> Resource&& { return std::move(r); }));
```

How do we fuse these implementations?

```
Resource visit(auto visitor) {
Resource result = visitor(resource);
return result;
}

Resource& visit(auto visitor) {
Resource& result = visitor(resource);
return result;
}

Resource&& visit(auto visitor) {
Resource&& visit(auto visitor) {
Resource&& visit(auto visitor) {
Resource&& result = visitor(resource);
return static_cast<Resource&&>(result);
}
```

```
decltype(auto) visit(auto visitor) {
    decltype(auto) result = visitor(resource);
    return static_cast<decltype(result)>(result);
}
```

```
#include <iostream>
    struct Resource {};
    struct Target {
        Target(const Resource&) { std::cout << 'a'; }</pre>
        Target(Resource&&) { std::cout << 'b'; }</pre>
 6
    };
    struct ResourceManager {
        Resource resource:
10
11
        decltype(auto) visit(auto visitor) {
12
            decltype(auto) result = visitor(resource);
            return static_cast<decltype(result)>(result);
13
14
15
   };
16
    int main() {
17
18
        ResourceManager rm;
        Target(rm.visit([](Resource& r) -> Resource& { return r; }));
19
        Target(rm.visit([](Resource& r) -> Resource { return r; }));
20
        Target(rm.visit([](Resource\& r) -> Resource\&\& { return std::move(r); }));
21
22
```

Q: What is the output of the program?

```
#include <iostream>
struct Resource {
    Resource() {}
    Resource(const Resource&) { std::cout << 'a'; }</pre>
};
struct ResourceManager {
    Resource resource;
    Resource visit(auto visitor) {
        Resource result = visitor(resource);
        return result;
};
struct Target { Target(const Resource&) {}; };
int main() {
    ResourceManager rm;
    Target(rm.visit([](Resource& r) -> Resource { return r; }));
```

godbolt.org/z/aK8f4x

19

20

Q: What is the output of the program?

```
#include <iostream>
   struct Resource {
        Resource() {}
        Resource(const Resource&) { std::cout << 'a'; }</pre>
   };
   struct ResourceManager {
        Resource resource;
        Resource visit(auto visitor) {
            Resource result = visitor(resource);
            return static cast<Resource>(result);
13
   };
14
   struct Target { Target(const Resource&) {}; };
16
   int main() {
18
        ResourceManager rm;
19
        Target(rm.visit([](Resource& r) -> Resource { return r; }));
20
```

godbolt.org/z/rhhM8a

2

5

10

11

12

15

17

```
struct Resource {
    [...]
    Resource(const Resource&) { std::cout << 'a'; }
};

Resource visit(auto visitor) {
    Resource result = visitor(resource);
    return static_cast<Resource>(result);
}
```

Neither RVO nor NRVO!

- → static_cast is not the name of a variable (c-style cast does not work either)
- → compiler cannot elide observable side effects of copy construction
- → "Solution"
 - → remove explicit cast, or
 - → remove side effect (std::cout)

```
template <typename T>
decltype(auto) visit(T visitor) {
    decltype(auto) result = visitor(resource);
    if constexpr (std::is_same_v<decltype(result), Resource&&>) {
        return std::move(result);
    } else {
        return result;
    }
}
```

...works for GCC (without auto concept), not for Clang though

```
template <typename T>
   static constexpr bool returns rref = std::is same v<std::invoke result t<T,

→ Resource&>, Resource&&>;

3
   template <typename T, std::enable_if_t<returns_rref<T>, int> = 0>
   decltype(auto) visit(T visitor) {
       decltype(auto) result = visitor(resource);
6
        return std::move(result);
8
9
10
   template <typename T, std::enable if t<not returns rref<T>, int> = 0>
   decltype(auto) visit(T visitor) {
11
12
       decltype(auto) result = visitor(resource);
       return result:
13
14
```

...still, no NRVO with Clang but this time due to the deduced return type!

```
template <typename T>
   static constexpr bool returns_rref = std::is_same_v<std::invoke result t<T,</pre>

→ Resource&>, Resource&&>;

3
   template <typename T, std::enable_if_t<returns_rref<T>, int> = 0>
   decltype(auto) visit(T visitor) {
        decltype(auto) result = visitor(resource);
6
        return std::move(result);
8
9
10
   template <typename T, std::enable if t<not returns rref<T>, int> = 0>
   auto visit(T visitor) -> decltype(visitor(resource)) {
11
12
        decltype(auto) result = visitor(resource);
        return result;
13
14
```

...now works for GCC and Clang!

```
#include <iostream>
struct Resource {
    Resource() {}
    Resource(const Resource&) { std::cout << 'a'; }</pre>
};
struct ResourceManager {
    Resource resource:
    template <tvpename T>
    static constexpr bool returns_rref = std::is_same_v<std::invoke_result_t<T,</pre>

→ Resource&>, Resource&&>;

    template <typename T, std::enable_if_t<returns_rref<T>, int> = 0>
    decltype(auto) visit(T visitor) {
        decltype(auto) result = visitor(resource);
        return std::move(result);
    template <typename T, std::enable if t<not returns rref<T>, int> = 0>
[...]
```

```

godbolt.org/z/e48EeT

...fails with GCC and Clang

Conclusion

(shamelessly copied from CppCon 2018: Hayun Ezra Chung "Forwarding Values... and Backwarding Them Too?")

Forwarding

- → Parameter Type: T&&
- → Function Argument: std::forward<E>(e)
- → Alternatively: static_cast<decltype(e)&&>(e)

Backwarding

- → Parameter Type: decltype(auto)
- → Function Argument: decltype(e)(e)
- → Alternatively: static_cast<decltype(e)>(e)*
